

Network Architecture

KRPUNE Native, Offline Real Estate Showcase Application

Project / Product	KRPUNE Native (krpune-native)	Version	1.0.0
Prepared By	Fute Services, Technical Review	Date	16 July 2026

1. Purpose

This document describes the network footprint of the KRPUNE Native mobile application, based on a full inspection of its source code.

2. Scope

Client-side mobile application only (Android and iOS). The application has no backend server of its own and performs no network activity during normal use.

3. Components Identified in the Codebase

Component	Status
End users / client devices	Present, Android/iOS phones and tablets running the application
Load balancers	Not present, no backend
Web / application servers	Not present, the app is fully bundled and offline
Databases	Not present, all content ships as local JSON files
Firewalls / DMZ	Not applicable, no server infrastructure to protect
VPN / remote access	Not present
External cloud services contacted at runtime	None
Third-party integrations / APIs	None

Note on Cloudinary references found in code

A small number of source files (Home, Amenities and Location screens) contain strings that resemble Cloudinary URLs. On inspection, these strings are used only as lookup keys passed into a local asset resolver, which matches the filename against a bundled asset map and returns the file already packaged inside the app. All such references were verified to resolve locally; the application does not contact Cloudinary, or any other external service, during normal use. A fallback exists in the resolver code that would stream from the URL only if a bundled asset were ever missing. This path is not exercised by the application as currently built.

4. Network Zones

There is no server-side infrastructure and no live network activity for this application. It is a fully self-contained, offline mobile application. Every screen, image, video and data file ships inside the installed application package.

5. Diagram

A visual architecture and data flow diagram is provided as a companion document: *Architecture and Data Flow Diagram*.

6. Notes

This document reflects what the current source code shows. If a separate backend, admin panel or content management system is used to prepare the bundled data before each build, that infrastructure sits outside this repository and should be documented separately by whoever manages it.
