

Data / Information Flow

KRPUNE Native, Offline Real Estate Showcase Application

Project / Product	KRPUNE Native (krpune-native)	Version	1.0.0
Prepared By	Fute Services, Technical Review	Date	16 July 2026

1. Purpose

This document describes how data moves through the KRPUNE Native mobile application, based on inspection of its source code.

2. Data Sources

- Bundled JSON files shipped inside the application (floor plans, amenities, mobility, transport, gallery, and VR tour data). These are static content captured at build time, not live user or third-party input.
- Media assets (images and video) bundled inside the application and resolved locally at runtime, not fetched from a network.
- No user-entered data anywhere in the application. No forms, no login, and no text input fields were found during the review.

3. Types of Data Handled

- ☐ Personally Identifiable Information (PII), none found
- ☐ Financial data, none
- ☐ Health data, none
- ☐ Authentication credentials, none, application has no login or accounts
- ☒ Business / operational data, project marketing content including floor plans, amenities, VR tour scenes, location and mobility information, and gallery images

4. Data Flow Description

1. The application launches and reads bundled JSON data directly from local application storage. No network call is made.
2. Screens (Home, Amenities, VR, Location, Gallery, Mobility, Unit Plan, and others) resolve each image or video reference against a locally bundled asset map and load the file directly from the installed application package.
3. For the VR and panorama viewer, the application writes a self-generated HTML file into its own local cache directory and loads it into an in-app WebView to render the 3D/360 viewer. No data leaves the device for this step.

4. No data is ever sent from the device to any server, and no data is ever pulled from a live server during normal use. This is a fully closed, on-device content flow.

5. Storage Points

Location	What is stored
Application bundle	Static JSON content and all media assets, shipped with the install package, read-only
Device cache directory	Temporary copies of self-generated HTML files for the WebView viewer, cleared with normal application cache clearing
Local database / persistent storage	None. No AsyncStorage or SecureStore usage was found. The application does not persist any user data.

6. Security Measures

- ☐ Encryption in transit, not applicable, no network calls are made during normal use
- ☐ Encryption at rest, not applicable, no sensitive data is stored on the device
- ☐ Access controls, not applicable, no accounts or data to control access to
- ☐ Data masking / anonymisation, not applicable, no personal data is collected

7. Third-Party Data Sharing

None. The application does not contact any external server or third party during normal use. A few image and video references in the code still carry Cloudinary-style identifiers left over from the original web application, but these are used only as filename keys for local lookup. See the accompanying Network Architecture document for detail.

8. Diagram

A visual version of this flow is provided as a companion document: *Architecture and Data Flow Diagram*.

9. Notes

This document reflects what the current source code shows for the mobile application itself. If floor plans or other bundled content are generated through a separate content management system before being packaged into the app, the data flow for that system should be documented separately by whoever manages it.
